

PRELIMINARY November 1996

LMX2301 PLLatinum[™] 160 MHz Frequency Synthesizer for RF Personal Communications

General Description

The LMX2301 is a high performance frequency synthesizer designed for RF operation up to 160 MHz. It is fabricated using National's ABiC IV BiCMOS process.

LMX2301, which employs the digital phase lock loop technique, combined with a high quality reference oscillator and a loop filter, provides the tuning voltage for the voltage controlled oscillator to generate a very stable, low noise local oscillator signal.

Serial data is transferred into the LMX2301 via a three line MICROWIRE $^{\rm TM}$ interface (Data, Enable, Clock). Supply voltage can range from 2.7V to 5.5V.

The LMX2301 features very low current consumption, typically 2 mA at 3V.

The LMX2301 is available in a TSSOP 20-pin surface mount plastic package.

Features

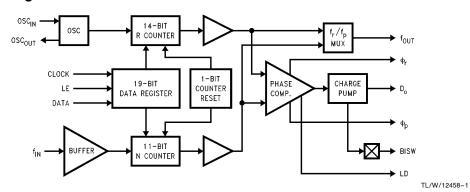

- RF operation up to 160 MHz
- 2.7V to 5.5V operation
- Low current consumption: $I_{CC} = 2 \text{ mA (typ) at } V_{CC} = 3V$
- Internal balanced, low leakage charge pump
- Small-outline, plastic, surface mount TSSOP, 0.173" wide package

Applications

- Analog Cellular telephone systems (AMPS, ETACS, NMT)
- Portable wireless communications (PCS/PCN, cordless)
- Other wireless communication systems

RRD-B30M126/Printed in U. S. A.

Pin Descriptions

operation as an oscillator. The input has a V _{CC} /2 input threshold and can be driven from an external CMOS or TTL logic gate. May also be from a reference oscillator. 3 OSC _{OUT} O Oscillator output. 4 V _P Power supply for charge pump. Must be ≥ V _{CC} . 5 V _{CC} Power supply for charge pump. Must be ≥ V _{CC} . 6 D _O O Internal charge pump output. Input may range from 2.7V to 5.5V. Bypass capacitors should be placed as close as possible to this pin and be connected directly to the ground plane. 6 D _O O Internal charge pump output. For connection to a loop filter for driving the input of an externa VCO. 7 GND Ground. 8 LD O Lock detect. Output provided to indicate when the VCO frequency is in "lock". When the loo locked, the pin's output is HIGH with narrow low pulses. 10 f _{IN} I RF buffer input. Small signal input from the VCO. 11 CLOCK I High impedance CMOS Clock input. Data is clocked in on the rising edge, into the various counters and registers. 13 DATA I Binary serial data input. Data entered MSB first. LSB is control bit. High impedance CMOS in the laptopy of the place of the shift registers is loaded into the appropriate latch (control bit dependent). Clock must be low when LE toggles high or low. See Serial Data Input Timing Diagram. 15 FC I Phase control select (with internal pull-up resistor). When FC is LOW, the polarity of the phase comparator and charge pump combination is reversed. 16 BISW O Analog switch output. When LE is HIGH, the analog switch is ON, routing the internal charge pump output through BISW (as well as through D _O).

Functional Block Diagram

TL/W/12458-3

Note 1: The power down function is gated by the charge pump to prevent any unwanted frequency jumps. Once the power down pin is brought low the part will go into power down mode when the charge pump reaches a TRI-STATE condition.

Absolute Maximum Ratings (Notes 1 and 2)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Power Supply Voltage

V_{CC} -0.3V to +6.5V V_P -0.3V to +6.5V

Voltage on Any Pin

with GND = 0V (V_I) -0.3V to V_{CC} +0.3V to rage Temperature Range (T_S) -65°C to +150°C

 $\begin{array}{ll} \mbox{Storage Temperature Range (T_S)} & -65^{\circ}\mbox{C to } +150^{\circ}\mbox{C} \\ \mbox{Lead Temperature (T_L) (solder, 4 sec.)} & +260^{\circ}\mbox{C} \end{array}$

Recommended Operating Conditions

Power Supply Voltage

 $\begin{array}{ccc} V_{CC} & 2.7V \text{ to } 5.5V \\ V_{P} & V_{CC} \text{ to } + 5.5V \end{array}$

Operating Temperature (T_A) -40° C to $+85^{\circ}$ C

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but do not guarantee specific performance limits. For guaranteed specifications and test conditions, see the Electrical Characteristics. The guaranteed specifications apply only for the test conditions listed.

Note 2: This device is a high performance RF integrated circuit with an ESD rating < 2 keV and is ESD sensitive. Handling and assembly of this device should only be done at ESD workstations.

Functional Description

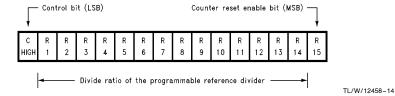

The simplified block diagram below shows the 19-bit data register, the 14-bit R Counter and the R15 Latch, and the 11-bit N Counter (intermediate latches are not shown). The data stream is clocked (on the rising edge) into the DATA input, MSB first. If the Control Bit (last bit input) is HIGH, the DATA is transferred into the R Counter (programmable reference divider) and the S Latch (power up counter reset). If the Control Bit (LSB) is LOW, the DATA is transferred into the N Counter (programmable divider).

TL/W/12458-1

PROGRAMMABLE REFERENCE DIVIDER (R COUNTER) AND COUNTER RESET (R15 LATCH)

If the Control Bit (last bit shifted into the Data Register) is HIGH, data is transferred from the 19-bit shift register into a 14-bit latch (which sets the 14-bit R Counter) and the 1-bit R15 Latch, which can be used to force an immediate load of the R and N counters during a cold power up condition. Serial data format is shown below.

14-BIT PROGRAMMABLE REFERENCE DIVIDER RATIO (R COUNTER)

Divide Ratio R	R 14	R 13	R 12	R 11	R 10	R 9	R 8	R 7	R 6	R 5	R 4	R 3	R 2	R 1
3	0	0	0	0	0	0	0	0	0	0	0	0	1	1
4	0	0	0	0	0	0	0	0	0	0	0	1	0	0
•	•	•	•	•	•	•	•	•	•	•	•	•	•	•
16383	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Notes: Divide ratios less than 3 are prohibited.

Divide ratio: 3 to 16383

R1 to R14: These bits select the divide ratio of the programmable reference divider.

C: Control bit (set to HIGH level to load R counter and R15 Latch)
Data is shifted in MSB first.

1-BIT COUNTER RESET (R15 LATCH)

Counter Reset	R 15
Remove Forced Load	0
Force Load State	1

The 1-bit counter reset latch controls whether the R and N counters are immediately forced to load conditions upon power up. If R[15] = HIGH, the N and R latch states are immediately read into the respective counters.

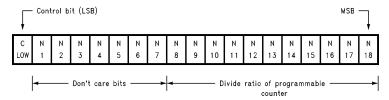

SUGGESTED PROGRAMMING SEQUENCE AFTER COLD POWER-UP

- 1. Program N counter with desired divide ratio.
- 2. Program R counter with R15=1 and desired divide ratio. (N and R counters hold at load state.)
- 3. Program R counter with R15=0 and desired divide ratio. (N and R counters start counting.)

Functional Description (Continued)

PROGRAMMABLE DIVIDER (N COUNTER)

The N counter consists of the 11-bit programmable counter. If the Control Bit (last bit shifted into the Data Register) is LOW, data is transferred from the 19-bit shift register into an 11-bit latch, which sets the 11-bit programmable Counter. Serial data format is shown below.

Note: R8 to R18: Programmable counter divide ratio control bits (3 to 2047)

7 LSB BITS OF N REGISTER

Divide	N	N	N	N	N	N	N
Ratio	7	6	5	4	3	2	1
X	Х	Х	Х	Х	Х	Х	

Note: X = Don't care state

11-BIT PROGRAMMABLE COUNTER DIVIDE RATIO

Divide Ratio N	N 18	N 17	N 16	N 15	N 14	N 13	N 12	N 11	N 10	N 9	N 8
3	0	0	0	0	0	0	0	0	0	1	1
4	0	0	0	0	0	0	0	0	1	0	0
•	•	•	•	•	•	•	•	•	•	•	•
2047	1	1	1	1	1	1	1	1	1	1	1

Note: Divide ratio: 3 to 2047 (Divide ratios less than 3 are prohibited)

EQUATION FOR OUTPUT FREQUENCY DETERMINATION

 $f_{\text{VCO}} = [N] \times f_{\text{OSC}} / R$

 f_{VCO} : Output frequency of external voltage controlled oscillator (VCO)

TL/W/12458-15

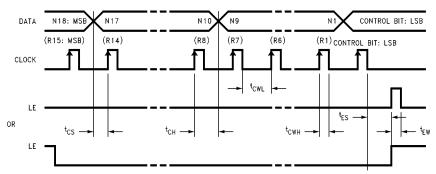

N: Preset divide ratio of binary 11-bit programmable counter (3 to 2047)

f_{OSC}: Output frequency of the external reference frequency oscillator

R: Preset divide ratio of binary 14-bit programmable reference counter (3 to 16383)

Functional Description (Continued)

SERIAL DATA INPUT TIMING

TL/W/12458-16

Notes: Parenthesis data indicates programmable reference divider data.

Data shifted into register on clock rising edge.

Data is shifted in MSB first.

Test Conditions: The Serial Data Input Timing is tested using a symmetrical waveform around $V_{CC}/2$. The test waveform has an edge rate of 0.6 V/ns with amplitudes of 2.2V @ $V_{CC}=2.7V$ and 2.6V @ $V_{CC}=5.5V$.

Phase Characteristics

In normal operation, the FC pin is used to reverse the polarity of the phase detector. Both the internal and any external charge pump are affected.

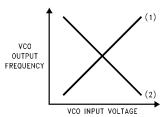

Depending upon VCO characteristics, FC pin should be set accordingly:

When VCO characteristics are like (1), FC should be set HIGH or OPEN CIRCUIT;

When VCO characteristics are like (2), FC should be set LOW.

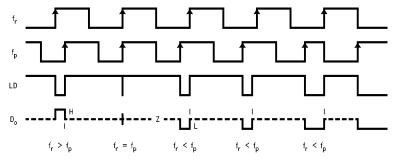

When FC is set HIGH or OPEN CIRCUIT, the monitor pin of the phase comparator input, f_{out} , is set to the reference divider output, f_r . When FC is set LOW, f_{out} is set to the programmable divider output, f_p .

VCO Characteristics

TL/W/12458-17

PHASE COMPARATOR AND INTERNAL CHARGE PUMP CHARACTERISTICS

TL/W/12458-18

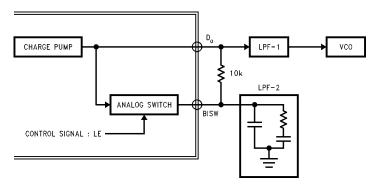

Notes: Phase difference detection range: -2π to $+2\pi$

The minimum width pump up and pump down current pulses occur at the D_0 pin when the loop is locked.

FC = HIGH

Analog Switch

The analog switch is useful for radio systems that utilize a frequency scanning mode and a narrow band mode. The purpose of the analog switch is to decrease the loop filter time constant, allowing the VCO to adjust to its new frequency in a shorter amount of time. This is achieved by adding another filter stage in parallel. The output of the charge pump is normally through the D_0 pin, but when LE is set HIGH, the charge pump output also becomes available at BISW. A typical circuit is shown below. The second filter stage (LPF-2) is effective only when the switch is closed (in the scanning mode).

TL/W/12458-19

Typical Crystal Oscillator Circuit

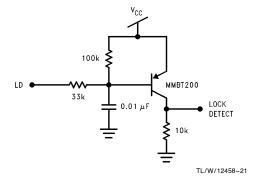

A typical circuit which can be used to implement a crystal oscillator is shown below.

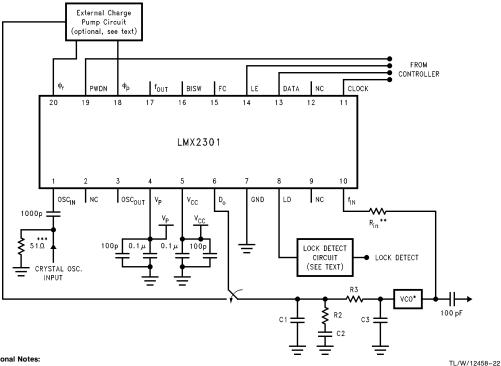

TI /W/12458-20

Typical Lock Detect Circuit

A lock detect circuit is needed in order to provide a steady LOW signal when the PLL is in the locked state. A typical circuit is shown below.

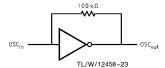

Typical Application Example

Operational Notes:

- VCO is assumed AC coupled.
- R_{IN} increases impedance so that VCO output power is provided to the load rather than the PLL. Typical values are 10 \$\Omega\$ to 200 \$\Omega\$ depending on the VCO power level. $f_{\mbox{\footnotesize{IN}}}$ RF impedance ranges from 40Ω to $100\Omega.$
- *** 50 Ω termination is often used on test boards to allow use of external reference oscillator. For most typical products a CMOS clock is used and no terminating resistor is required. OSC_{IN} may be AC or DC coupled. AC coupling is recommended because the input circuit provides its own bias. (See Figure below)

Application Hints:

Proper use of grounds and bypass capacitors is essential to achieve a high level of performance.

Crosstalk between pins can be reduced by careful board layout.

This is an electrostatic sensitive device. It should be handled only at static free work stations.

Application Information

LOOP FILTER DESIGN

A block diagram of the basic phase locked loop is shown.

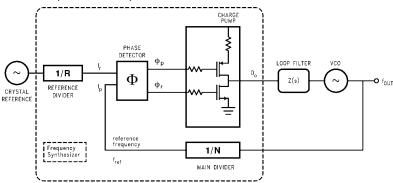

FIGURE 1. Basic Charge Pump Phase Locked Loop

TL/W/12458-24

An example of a passive loop filter configuration, including the transfer function of the loop filter, is shown in *Figure 2*.

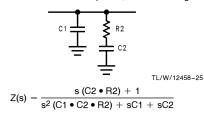

FIGURE 2. 2nd Order Passive Filter

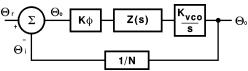

Define the time constants which determine the pole and zero frequencies of the filter transfer function by letting

$$T2 = R2 \cdot C2 \tag{1a}$$

and

$$T1 = R2 \bullet \frac{C1 \bullet C2}{C1 + C2}$$
 (1b)

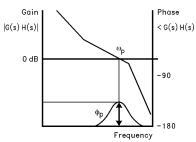

The PLL linear model control circuit is shown along with the open loop transfer function in Figure 3. Using the phase detector and VCO gain constants $[K\phi$ and $K_{VCO}]$ and the loop filter transfer function [Z(s)], the open loop Bode plot can be calculated. The loop bandwidth is shown on the Bode plot (ωp) as the point of unity gain. The phase margin is shown to be the difference between the phase at the unity gain point and $-180^{\circ}.$

TL/W/12458-27

Open Loop Gain =
$$\theta_i/\theta_e$$
 = H(s) G(s) = K ϕ Z(s) K_{VCO}/Ns

Closed Loop Gain = θ_0/θ_i = G(s)/[1 + H(s) G(s)]

TL/W/12458-26

FIGURE 3. Open Loop Transfer Function

Thus we can calculate the 3rd order PLL Open Loop Gain in terms of frequency

$$\left. \mathsf{G}(s) \bullet \mathsf{H}(s) \right|_{S \ = \ j} \bullet_{\omega} = \frac{- \, \mathsf{K} \varphi \bullet \mathsf{K}_{VCO} \left(1 \ + \ j \omega \bullet \mathsf{T2} \right)}{\omega^2 \mathsf{C1} \bullet \mathsf{N} (1 \ + \ j \omega \bullet \mathsf{T1})} \bullet_{}^{} \frac{\mathsf{T1}}{\mathsf{T2}} \quad (2)$$

From equation 2 we can see that the phase term will be dependent on the single pole and zero such that

$$\varphi(\omega)=\tan^{-1}\left(\omega\bullet T2\right)-\tan^{-1}\left(\omega\bullet T1\right)+180^{\circ} \quad \mbox{(3)}$$
 By setting

$$\frac{d\phi}{d\omega} = \frac{T2}{1 + (\omega \bullet T2)^2} - \frac{T1}{1 + (\omega \bullet T1)^2} = 0 \tag{4}$$

we find the frequency point corresponding to the phase inflection point in terms of the filter time constants T1 and T2. This relationship is given in equation 5.

$$\omega_{\mathsf{p}} = 1/\sqrt{\mathsf{T2} \bullet \mathsf{T1}} \tag{5}$$

For the loop to be stable the unity gain point must occur before the phase reaches -180 degrees. We therefore want the phase margin to be at a maximum when the magnitude of the open loop gain equals 1. Equation 2 then gives

$$C1 = \frac{\mathsf{K} \phi \bullet \mathsf{K}_{VCO} \bullet \mathsf{T1}}{\omega_p^2 \bullet \mathsf{N} \bullet \mathsf{T2}} \bigg\| \frac{(1 + j\omega_p \bullet \mathsf{T2})}{(1 + j\omega_p \bullet \mathsf{T1})} \bigg\| \tag{6}$$

Application Information (Continued)

Therefore, if we specify the loop bandwidth, ω_{p} , and the phase margin, ϕ_D , Equations 1 through 6 allow us to calculate the two time constants, T1 and T2, as shown in equations 7 and 8. A common rule of thumb is to begin your design with a 45° phase margin.

$$T1 = \frac{\sec\varphi_p - \tan\varphi_p}{\omega_p} \eqno(7)$$

$$T2 = \frac{1}{\omega_p^2 \bullet T1} \eqno(8)$$

$$T2 = \frac{1}{\omega_p^2 \bullet T1} \tag{8}$$

From the time constants T1, and T2, and the loop bandwidth, $\omega_{\text{p}}\text{,}$ the values for C1, R2, and C2 are obtained in equations 9 to 11.

$$C1 = \frac{T1}{T2} \bullet \frac{K\phi \bullet K_{VCO}}{\omega_p^2 \bullet N} \sqrt{\frac{1 + (\omega_p \bullet T2)^2}{1 + (\omega_p \bullet T1)^2}} \tag{9}$$

$$C2 = C1 \bullet \left(\frac{T2}{T1} - 1\right) \tag{10}$$

$$R2 = \frac{T2}{C2} \tag{11}$$

Voltage Controlled Oscillator (VCO) K_{VCO} (MHz/V) Tuning Voltage constant. The fre-

quency vs voltage tuning ratio. Phase detector/charge pump gain Kφ (mA) constant. The ratio of the current out-

put to the input phase differential. Main divider ratio. Equal to RFopt/fref

RFopt (MHz) Radio Frequency output of the VCO at which the loop filter is optimized.

fref (kHz) Frequency of the phase detector inputs. Usually equivalent to the RF channel spacing.

In choosing the loop filter components a trade off must be made between lock time, noise, stability, and reference spurs. The greater the loop bandwidth the faster the lock time will be, but a large loop bandwidth could result in higher reference spurs. Wider loop bandwidths generally improve close in phase noise but may increase integrated phase noise depending on the reference input, VCO and division ratios used. The reference spurs can be reduced by reducing the loop bandwidth or by adding more low pass filter stages but the lock time will increase and stability will decrease as a result.

THIRD ORDER FILTER

A low pass filter section may be needed for some applications that require additional rejection of the reference sidebands, or spurs. This configuration is given in Figure 4. In order to compensate for the added low pass section, the component values are recalculated using the new open loop unity gain frequency. The degradation of phase margin caused by the added low pass is then mitigated by slightly increasing C1 and C2 while slightly decreasing R2.

The added attenuation from the low pass filter is:

ATTEN =
$$20 \log[(2\pi f_{ref} \cdot R3 \cdot C3)^2 + 1]$$
 (12)

Defining the additional time constant as

$$T3 = R3 \bullet C3 \tag{13}$$

Then in terms of the attenuation of the reference spurs added by the low pass pole we have

T3 =
$$\sqrt{\frac{10^{\text{ATTEN/20}} - 1}{(2\pi \bullet f_{\text{ref}})^2}}$$
 (14)

We then use the calculated value for loop bandwidth ω_{C} in equation 11, to determine the loop filter component values in equations 15-17. ω_{C} is slightly less than $\omega_{\text{p}},$ therefore the frequency jump lock time will increase.

$$T2 = \frac{1}{\omega_c^2 \bullet (T1 + T3)} \tag{15}$$

$$\omega_{\text{C}} = \frac{\tan\phi \bullet (T1 + T3)}{[(T1 + T3)^2 + T1 \bullet T3]} \bullet \left[\sqrt{1 + \frac{(T1 + T3)^2 + T1 \bullet T3}{[\tan\phi \bullet (T1 + T3)]^2}} - 1 \right] \tag{16}$$

$$C1 = \frac{T1}{T2} \bullet \frac{K\phi \bullet K_{VCO}}{\omega_{c}^{2} \bullet N} \bullet \left[\frac{(1 + \omega_{c}^{2} \bullet T2^{2})}{(1 + \omega_{c}^{2} \bullet T1^{2})(1 + \omega_{c}^{2} \bullet T3^{2})} \right]^{\frac{1}{2}}$$
(17)

Application Information (Continued)

EXTERNAL CHARGE PUMP

The LMX PLLatinum series of frequency synthesizers are equipped with an internal balanced charge pump as well as outputs for driving an external charge pump. Although the superior performance of NSC's on board charge pump eliminates the need for an external charge pump in most applications, certain system requirements are more stringent. In these cases, using an external charge pump allows the designer to take direct control of such parameters as charge pump voltage swing, current magnitude, TRI-STATE leakage, and temperature compensation.

One possible architecture for an external charge pump current source is shown in Figure 9. The signals φ_p and φ_r in the diagram, correspond to the phase detector outputs of the LMX2301 frequency synthesizer. These logic signals are converted into current pulses, using the circuitry shown in Figure 9, to enable either charging or discharging of the loop filter components to control the output frequency of the DLI

Referring to Figure 9, the design goal is to generate a 5 mA current which is relatively constant to within 0.5V of the power supply rail. To accomplish this, it is important to establish as large of a voltage drop across R5, R8 as possible without saturating Q2, Q4. A voltage of approximately 300 mV provides a good compromise. This allows the current source reference being generated to be relatively repeatable in the absence of good Q1, Q2/Q3, Q4 matching. (Matched transistor pairs is recommended.) The φp and φr outputs are rated for a maximum output load current of 1 mA while 5 mA current sources are desired. The voltages developed across R4, 9 will consequently be approximately 258 mV, or 42 mV < R8, 5, due to the current density differences $\{0.026^*1n~(5~mA/1~mA)\}$ through the Q1, Q2/Q3, Q4 mairs

In order to calculate the value of R7 it is necessary to first estimate the forward base to emitter voltage drop (Vfn,p) of the transistors used, the V_{OL} drop of ϕp , and the V_{OH} drop of ϕr 's under 1 mA loads. (ϕp 's $V_{OL} < 0.1 V$ and ϕr 's $V_{OH} < 0.1 V$.)

Knowing these parameters along with the desired current allow us to design a simple external charge pump. Separating the pump up and pump down circuits facilitates the nodal analysis and give the following equations.

$$\begin{split} R_4 &= \frac{V_{R5} - V_T \bullet In \left(\frac{i_{source}}{i_p \, max}\right)}{i_{source}} \\ R_9 &= \frac{V_{R8} - V_T \bullet In \left(\frac{i_{sink}}{i_n \, max}\right)}{i_{sink}} \\ R_5 &= \frac{V_{R5}}{i_p \, max} \\ R_8 &= \frac{V_{R8}}{i_{r \, max}} \\ R_6 &= \frac{(V_p - V_{VOL\varphi p}) - (V_{R5} + V_{fp})}{i_p \, max} \\ R_7 &= \frac{(V_p - V_{VOH\varphi r}) - (V_{R8} + V_{fn})}{i_{r \, max}} \end{split}$$

EXAMPLE

Typical Device Parameters $\beta_n = 100, \beta_p = 50$

Design Parameters

Typical System Parameters
$$V_P = 5.0V$$
;

$$V_{cntl} = 0.5V - 4.5V;$$

$$V_{cntl} = 0.5V = 4.5V,$$

 $V_{\phi p} = 0.0V; V_{\phi r} = 5.0V$

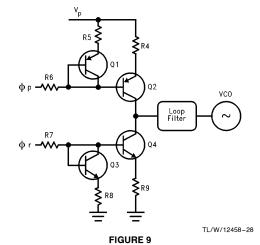

$$V_{\phi p} = 0.0V$$
, $V_{\phi r} = 5.0V$
 $I_{SINK} = I_{SOURCE} = 5.0 \text{ mA}$;

$$V_{fn} = V_{fp} = 0.8V$$

$$I_{rmax} = I_{pmax} = 1 \text{ mA}$$

$$V_{R8} = V_{R5} = 0.3V$$

$$V_{OL\phi p} = V_{OH\phi r} = 100 \text{ mV}$$

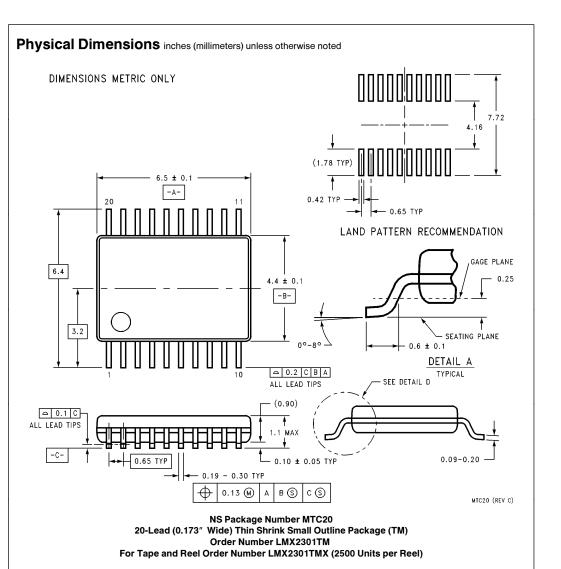

Therefore select

$$R_4 = R_9 = \frac{0.3V - 0.026 \bullet 1n(5.0 \text{ mA}/1.0 \text{ mA})}{5 \text{ mA}} = 51.6\Omega$$

$$R_5 = \frac{\text{0.3V}}{\text{1.0 mA}} = 300\Omega$$

$$R_8 = \frac{0.3V}{1.0 \text{ mA}} = 300\Omega$$

$$R_6 = R_7 = \frac{(5V - 0.1V) - (0.3V + 0.8V)}{1.0 \text{ mA}} = 3.8 \text{ k}\Omega$$

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

- 1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
- 2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
