### 2.25MHz 600mA/1000mA Dual Step Down Converter In Small 3x3mm QFN Package

## FEATURES

- High Efficiency-up to $95 \%$
- $\mathrm{V}_{\mathrm{IN}}$ Range From 2.5 V to 6 V
- 2.25 MHz Fixed Frequency Operation
- Output Current 600 mA and 1000 mA
- Adjustable Output Voltage From 0.6 V to $\mathrm{V}_{\mathrm{IN}}$
- EasyScale ${ }^{\text {TM }}$ Optional One Pin Serial Interface for Dynamic Output Voltage Adjustment
- Power Save Mode at Light Load Currents
- $180^{\circ}$ Out of Phase Operation
- Output Voltage Accuracy in PWM Mode $\pm 1 \%$
- Typical $32 \mu \mathrm{~A}$ Quiescent current for both Converter
- $100 \%$ Duty Cycle for Lowest Dropout
- Available in a $10-\mathrm{Pin}$ QFN ( $3 \times 3 \mathrm{~mm}$ )

## APPLICATIONS

- Cell Phones, Smart-phones
- PDAs, Pocket PCs
- OMAPTM and Low Power DSP Supply
- Portable Media Players
- Digital Radio
- Digital Cameras

## DESCRIPTION

The TPS62420 device is a synchronous dual step-down DC-DC converter optimized for battery powered portable applications. It provides two independent output voltage rails powered by 1 -cell Li-lon or 3 -cell $\mathrm{NiMH} / \mathrm{NiCD}$ batteries. The device is also suitable to operate from a standard 3.3 V or 5 V voltage rail.
With an input voltage range of 2.5 V to 6 V the TPS62420 is ideal to power portable applications like smart phones, PDA's and other portable equipment.
With the EASY SCALE serial interface the output voltages can be modified during operation. It therefore supports Dynamic Voltage Scaling for low power DSP and processors.
The TPS62420 operates at 2.25 MHz fixed switching frequency and enter the Power Save Mode operation at light load currents to maintain high efficiency over the entire load current range. For low noise applications the devices can be forced into fixed frequency PWM mode by pulling the MODE/DATA pin high. In the shutdown mode, the current consumption is reduced to $1.2 \mu \mathrm{~A}$. The device allows the use of small inductors and capacitors to achieve a small solution size.

The TPS62420 is available in a 10-pin leadless package ( $3 \times 3 \mathrm{~mm}$ QFN)

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

(1) Stresses beyond those listed under absolute maximum ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under recommended operating conditions is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
(2) All voltage values are with respect to network ground terminal.
(3) The human body model is a 100 pF capacitor discharged through a $1.5 \mathrm{k} \Omega$ resistor into each pin. The machine model is a 200 pF capacitor discharged directly into each pin.

| ADJ2 | 1 | 1 | Input to adjust output voltage of converter 2. In adjustable version (TPS62420) connect a external resistor divider between VOUT2, this pin and GND to set output voltage between 0.6 V and VIN. If EasyScale ${ }^{\text {TM }}$ Interface is used for converter 2, this pin must be directly connected to the output. |
| MODE/DATA | 2 | 1 | This Pin has 2 functions: |
|  |  |  | 1. Operation Mode selection: With low level, Power Save Mode is enabled where the device operates in PFM mode at light loads and enters automatically PWM mode at heavy loads. Pulling this PIN to high forces the device to operate in PWM mode over the whole load range. |
|  |  |  | 2. EasyScale ${ }^{\text {TM }}$ Interface function: One wire serial interface to change the output voltage of both converters. The pin has an open drain output to provide an acknowledge condition if requested. The current into the open drain output stage may not exceed 500 mA . The interface is active if either EN1 or EN2 is high. |
| VIN | 3 | 1 | Supply voltage, connect to VBAT, 2.5 V to 6V |
| FB1 | 4 | I | Direct feedback voltage sense input of converter 1, connect directly to Vout 1. An internal feed forward capacitor is connected between this pin and the error amplifier. In case of fixed output voltage versions or when the Interface is used, this pin is connected to an internal resistor divider network. |
| DEF_1 | 5 | I/O | This pin defines the output voltage of converter 1. The pin acts in TPS62420 as an analog input for output voltage setting via external resistors. In fixed default output voltage versions this pin is a digital input to select between two fixed default output voltages. <br> In TPS62420 an external resistor network needs to be connected to this pin to adjust the default output voltage. |

## DETAILED DESCRIPTION

## OPERATION

The TPS62420 includes two synchronous step-down converters. The converters operate with typically 2.25 MHz fixed frequency pulse width modulation (PWM) at moderate to heavy load currents. If Power Safe Mode is enabled, the converters automatically enter Power Save Mode at light load currents and operate in PFM (Pulse Frequency Modulation). During PWM operation the converters use a unique fast response voltage mode controller scheme with input voltage feed-forward to achieve good line and load regulation allowing the use of small ceramic input and output capacitors. At the beginning of each clock cycle initiated by the clock signal, the P-channel MOSFET switch is turned on and the inductor current ramps up until the comparator trips and the control logic turns off the switch.

Each converter integrates two current limits, one in the P-channel MOSFET and another one in the N-channel MOSFET. When the current in the P-channel MOSFET reaches its current limit, the P-channel MOSFET is turned off and the N -channel MOSFET is turned on. If the current in the N -channel MOSFET is above the N-MOS current limit threshold, the N-channel MOSFET remains on until the current drops below its current limit. The two DC-DC converters operate synchronized to each other. A $180 \hat{A}^{\circ}$ phase shift between converter 1 and converter 2 decreases the input RMS current.

## Converter 1

In the adjustable output voltage version TPS62420 the converter 1 output voltage can be set via an external resistor network on PIN DEF_1, which operates as an analog input. In this case, the output voltage can be set in the range of 0.6 V to VIN V . The FB1 Pin must be directly connected to the converter 1 output voltage VOUT1. It feeds back the output voltage directly to the regulation loop.

The output voltage of converter 1 can also be changed by the Easy Scale serial Interface. This makes the device very flexible for output voltage adjustment. In this case, the device uses an internal resistor network.

## Converter 2

In the adjustable output voltage version TPS62420, the converter 2 output voltage is set by an external resistor divider connected to ADJ2 Pin.
It is also possible to change the output voltage of converter 2 via the EasyScale Interface. In this case, the ADJ2 Pin must be directly connected to converter 2 output voltage VOUT2. At TPS62420 no external resistor network may be connected.

## DETAILED DESCRIPTION (continued)

## POWER SAVE MODE

The Power Save Mode is enabled with Mode/Data Pin set to 0 for both converters. If the load current of a converter decreases, this converter will enter Power Save Mode operation automatically. The transition to Power Save Mode of a converter is independent from the operating condition of the other converter. During Power Save Mode the converter operates with reduced switching frequency in PFM mode and with a minimum quiescent current to maintain high efficiency. The converter will position the output voltage in PFM mode to typically 1.01 xVOUT . This voltage positioning feature minimizes voltage drops caused by a sudden load step.
In order to optimize the converter efficiency at light load the average inductor current is monitored. The device changes from PWM Mode to Power Save Mode, if in PWM mode the inductor current falls below a certain threshold. The typical output current threshold depends on VIN and can be calculated according to Equation 1 for each converter.

Equation 1): Average output current threshold to enter PFM Mode

$$
\begin{equation*}
\text { IOUT_PFM_enter }=\frac{\mathrm{VIN}_{\text {DCDC }}}{32 \Omega} \tag{1}
\end{equation*}
$$

Equation 2: Average output current threshold to leave PFM Mode

$$
\begin{equation*}
\text { IOUT_PFM_leave }=\frac{\mathrm{VIN}_{\text {DCDC }}}{24 \Omega} \tag{2}
\end{equation*}
$$

In order to keep the output voltage ripple in Power Save Mode low, the output voltage is monitored with a single threshold comparator (skip comparator). As the output voltage falls below the skip comparator threshold (skip comp) of $1.01 \times$ VOUTnominal, the corresponding converter starts switching for a minimum time period of typ. $1 \mu \mathrm{~s}$ and provides current to the load and the output capacitor. Therefore the output voltage will increase and the device maintains switching until the output voltage trips the skip comparator threshold (skip comp) again. At this moment all switching activity is stopped and the quiescent current is reduced to minimum. The load is supplied by the output capacitor until the output voltage has dropped below the threshold again. Hereupon the device starts switching again. The Power Save Mode is left and PWM Mode entered in case the output current exceeds the current IOUT_PFM_leave or if the output voltage falls below a second comparator threshold, called skip comparator low (Skip Comp Low) threshold. This skip comparator low threshold is set to -2\% below nominal Vout, and enables a fast transition from Power Save Mode to PWM Mode during a load step. In Power Save Mode the quiescent current is reduced typically to $19 \mu \mathrm{~A}$ for one converter and $32 \mu \mathrm{~A}$ for both converters active. This single skip comparator threshold method in Power Save Mode results in a very low output voltage ripple. The ripple depends on the comparator delay and the size of the output capacitor. Increasing output capacitor values will minimize the output ripple. The Power Save Mode can be disabled through the MODE/DATA pin set to high. Both converters will then operate in fixed PWM mode. Power Save Mode Enable/Disable applies to both converters.

## Dynamic Voltage Positioning

This feature reduces the voltage under/overshoots at load steps from light to heavy load and vice versa. It is activated in Power Save Mode operation. It provides more headroom for both, the voltage drop at a load step and the voltage increase at a load throw-off. This improves load transient behavior.

At light loads, in which the converter operate in PFM Mode, the output voltage is regulated typically $1 \%$ higher than the nominal value. In case of a load transient from light load to heavy load, the output voltage will drop until it reaches the skip comparator low threshold set to $-2 \%$ below the nominal value and enters PWM mode. During a load throw off from heavy load to light load, the voltage overshoot is also minimized due to active regulation turning on the N -channel switch.

## Soft Start

The two converters have an internal soft start circuit that limits the inrush current during start-up. During soft start, the output voltage ramp up is controlled as shown in Figure 27.

Figure 27. Soft Start

## 100\% Duty Cycle Low Dropout Operation

The converters offer a low input to output voltage difference while still maintaining operation with the use of the $100 \%$ duty cycle mode. In this mode the P-channel switch is constantly turned on. This is particularly useful in battery-powered applications to achieve longest operation time by taking full advantage of the whole battery voltage range. I.e. The minimum input voltage to maintain regulation depends on the load current and output voltage and can be calculated as:

$$
\begin{equation*}
\mathrm{Vin}_{\min }=\text { Vout }_{\text {max }}+\text { lout }_{\text {max }} \times\left(\text { RDSon }_{\text {max }}+\mathrm{R}_{\mathrm{L}}\right) \tag{3}
\end{equation*}
$$

With:
lout $_{\text {max }}=$ maximum output current plus inductor ripple current
RDSon $_{\text {max }}=$ maximum P-channel switch RDSon
$R_{L}=D C$ resistance of the inductor
Vout $_{\text {max }}=$ nominal output voltage plus maximum output voltage tolerance
With decreasing load current, the device automatically switches into pulse skipping operation in which the power stage operates intermittently based on load demand. By running cycles periodically the switching losses are minimized and the device runs with a minimum quiescent current maintaining high efficiency.

## DETAILED DESCRIPTION (continued)

## Under-Voltage Lockout

The under voltage lockout circuit prevents the device from malfunctioning at low input voltages and from excessive discharge of the battery and disables the converters. The under-voltage lockout threshold is typically 1.5 V , max 2.35 V . In case the default register values are overwritten by the Interface, the new values in the registers REG_DEF_1_Low and REG_DEF_2 remain valid as long the supply voltage does not fall under the Under-Voltage Lockout threshold independent whether the converters are disabled.

## MODE SELECTION

The MODE/DATA pin allows mode selection between forced PWM Mode and power Save Mode for both converts. Furthermore this pin is a multipurpose pin and provides beside Mode selection a one Pin interface to receive serial data from a host to set the output voltage. This is described in the section Easy Scale Interface.
Connecting this pin to GND enables the automatic PWM and power save mode operation. The converters operates in fixed frequency PWM mode at moderate to heavy loads and in the PFM mode during light loads, maintaining high efficiency over a wide load current range.
Pulling the MODE/DATA pin high forces both converters to operate constantly in the PWM mode even at light load currents. The advantage is the converters operate with a fixed frequency that allows simple filtering of the switching frequency for noise sensitive applications. In this mode, the efficiency is lower compared to the power save mode during light loads. For additional flexibility it is possible to switch from power save mode to forced PWM mode during operation. This allows efficient power management by adjusting the operation of the converter to the specific system requirements.

In case the operation mode will be changed from forced PWM mode (MODE/DATA = high) to Power Save Mode Enable (MODE/DATA $=0$ ) the Power Save Mode will be enabled after a delay time of typically $\mathrm{t}_{\text {timeout }}$, which is max. $520 \mu \mathrm{~s}$.
The forced PWM Mode operation is enabled immediately with Pin MODE/DATA set to 1.

## ENABLE

The device has for each converter a separate EN pin to start up each converter independently. If EN1, EN2 are set to high, the corresponding converter starts up with soft start as previously described.
Pulling EN1 and EN2 pin low forces the device into shutdown, with a shutdown quiescent current of typically $1.2 \mu \mathrm{~A}$. In this mode, the P and N -Channel MOSFETs are turned-off and the entire internal control circuitry is switched-off. For proper operation the EN1 and EN2 pins must be terminated and must not be left floating.

## DEF_1 PIN FUNCTION

The DEF_1 pin is dedicated to converter 1 and works as an analog input for adjustable output voltage setting. Connecting an external resistor network to this pin adjusts the default output voltage to any value starting from 0.6 V to $\mathrm{V}_{\mathrm{IN}}$.

## $180^{\circ}$ OUT OF PHASE OPERATION

In PWM Mode the converters operate with a $180^{\circ}$ turn on phase shift of the PMOS (high side) transistors. It prevents the high side switches of both converters to be turned on simultaneously and smoothens therefore the input current. This feature reduces the surge current drawn from the supply.

## SHORT-CIRCUIT PROTECTION

Both outputs are short circuit protected with maximum output current $=\mathrm{l}_{\text {LIMF }}(\mathrm{P}-\mathrm{MOS}$ and $\mathrm{N}-\mathrm{MOS})$. Once the PMOS switch reaches its current limit, it will be turned off and the NMOS turned on. The PMOS only turns on again, once the current in the NMOS decreased below the NMOS current limit.

## THERMAL SHUTDOWN

As soon as the junction temperature, $\mathrm{T}_{\mathrm{J}}$, exceeds typically $150^{\circ} \mathrm{C}$ the device goes into thermal shutdown. In this mode, the P and N -Channel MOSFETs are turned-off. The device continues its operation when the junction temperature falls below the thermal shutdown hysteresis again.

## DETAILED DESCRIPTION (continued)

## EasyScale ${ }^{\text {TM }}$ : One Pin Serial Interface for Dynamic Output Voltage Adjustment

## General

EasyScale is a simple but very flexible one pin interface to configure the output voltage of both DC/DC converters. The interface is based on a master - slave structure, where the master is typically a $\mu$ Controller or Application processor. Figure 28 and Table 2 give an overview of the protocol. The protocol consists of a device specific address byte and a data byte. The device specific address byte is fixed to 4 E hex. The data byte consists of five bit for information, two address bits and the RFA bit. RFA bit set to high indicates the Request For Acknowledge condition. The Acknowledge condition is only applied if the protocol was received correctly.
The advantage of EasyScale compared to other one pin interfaces is that its bit detection is in a large extent independent from the bit transmission rate. It can automatically detect bit rates between $1.7 \mathrm{kBit} / \mathrm{sec}$ and up to $160 \mathrm{kBit} / \mathrm{sec}$. Furthermore, the interface is shared with the Mode/Data Pin and requires therefore no additional pin.

## Protocol

All bits are transmitted MSB first and LSB last. Figure 29 shows the protocol without acknowledge request (bit RFA $=0$ ), Figure 30 with acknowledge (bit RFA $=1$ ) request.
Prior to both bytes, device address byte and data byte, a start condition needs to be applied. For this, the Mode/Data pin need be pulled high for at least $\mathrm{t}_{\text {start }}$ before the bit transmission starts with the falling edge. In case the Mode/Data line was already at high level (forced PWM Mode selection) no start condition need be applied prior the device address byte.
The transmission of each byte needs to be closed with an End Of Stream condition for at least $\mathrm{T}_{\text {EOS }}$.

## Addressable Registers

In TPS62420 two registers with a data content of 5 bits can be addressed to change the output voltage of both converters. With 5 bit data content, 32 different values for each register are available. Table 1 shows the addressable registers if DEF_1 pin acts as analog input with external resistors connected.
The available output voltages for converter 1 are shown in Table 3, for converter 2 in Table 4. To generate these output voltages, a precise internal resistor divider network is used, which makes external resistors unnecessary and results therefore in an higher output voltage accuracy and less board space.
The Interface is activated if at least one of the converters is enabled (EN1 or EN2 is high). After the Startup-time $t_{\text {start }}(170 \mu \mathrm{~s})$ the interface is ready for data reception.

Table 1. Addressable Registers for Adjustable Output Voltage Devices

| REGISTER | DESCRIPTION | A1 | A0 | D4 | D3 | D2 | D1 | D0 |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| REG_DEF_1_Low | Converter 1 output voltage setting | 0 | 0 | TPS62420 see Table 3 |  |  |  |  |

## Bit Decoding

The bit detection is based on a PWM scheme, where the criterion is the relation between $t_{\text {LOW }}$ and $t_{\text {HIGH. }}$. It can be simplified to:

High Bit: $t_{\text {High }}>t_{\text {Low }}$, but with $t_{\text {High }}$ at least $2 x t_{\text {Low }}$, see Figure 31
Low Bit: tLow> tHigh, but with tLow at least $2 x$ tHigh, see Figure 31
The bit detection starts with a falling edge on the MODED/DATA pin and ends with the next falling edge. Depending on the relation between $\mathrm{t}_{\text {Low }}$ and $\mathrm{t}_{\text {High }}$ a 0 or 1 is detected.

## Acknowledge

The Acknowledge condition is only applied if:

- Acknowledge is requested by a set RFA bit
- The transmitted device address matches with the device address of the device
- 16 bits were received correctly

In this case, the device turns on the internal ACKN-MOSFET and pulls the MODE/DATA pin low for the time tACKN, which is max. $520 \mu \mathrm{~s}$. The Acknowledge condition is valid after an internal delay time $\mathrm{t}_{\text {valack. }}$. This means the internal ACKN-MOSFET is turned on after $\mathrm{t}_{\text {valAck }}$, when the last falling edge of the protocol was detected. The master controller keeps the line low during this time.

The master device can detect the acknowledge condition with it's input by releasing the MODE/DATA pin after tvalACK and read back a 0 .
In case of an invalid device address or not correctly received protocol, no acknowledge condition will be applied, thus the internal MOSFET will not be turned on and the external pullup resistor pulls MODE/DATA pin high after $\mathrm{t}_{\text {valAck. }}$. The MODE/DATA pin can be used again after the acknowledge condition ends.

## NOTE:

The acknowledge condition may only be requested in case the master device has an open drain output.
In case of a push pull output stage it is recommended to use a series resistor in the MODE/DATA line to limit the current to $500 \mu \mathrm{~A}$ in case of an accidentally requested acknowledge to protect the internal ACKN-MOSFET.

## MODE Selection

Because of the MODE/DATA pin is used for two functions, interface and a MODE selection, the device needs to determine when it has to decode the bit stream or to change the operation mode.
The device enters forced PWM mode operation immediately whenever the MODE/DATA pin turns to high level. The device stays also in forced PWM mode during the whole time of a protocol reception.
With a falling edge on the MODE/DATA pin the device starts bit decoding. If the MODE/DATA pin stays low for at least $t_{\text {timeout }}$, the device get's an internal timeout and Power Save Mode operation is enabled.
A protocol which is sent within this time will be ignored, because the falling edge for the Mode change will be first interpreted as start of the first bit. In this case it is recommended to send first the protocol and change at the end of the protocol to Power Save Mode.

## APPLICATION INFORMATION

## OUTPUT VOLTAGE SETTING

## Converter1 Adjustable Default Output Voltage Setting:TPS62420

The output voltage can be calculated to:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{OUT}}=\mathrm{V}_{\mathrm{REF}} \times\left(1+\frac{\mathrm{R}_{11}}{R_{12}}\right) \text { with an internal reference voltage } \mathrm{V}_{\text {REF }} \text { typical } 0.6 \mathrm{~V} \tag{4}
\end{equation*}
$$

To keep the operating current to a minimum, it is recommended to select $R_{12}$ within a range of $180 \mathrm{k} \Omega$ to $360 \mathrm{k} \Omega$. The sum of $R_{12}$ and $R_{11}$ should not exceed $\sim 1 \mathrm{M} \Omega$.
Route the DEF_1 line away from noise sources, such as the inductor or the SW1 line. The FB1 line needs to be directly connected to the output capacitor.

## Converter 2 - TPS62420

The default output voltage of converter 2 can be set by an external resistor network.
The output voltage can be calculated to:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{OUT}}=\mathrm{V}_{\mathrm{REF}} \times\left(1+\frac{\mathrm{R}_{21}}{\mathrm{R}_{22}}\right) \text { with an internal reference voltage } \mathrm{V}_{\mathrm{REF}} \text { typical } 0.6 \mathrm{~V} \tag{5}
\end{equation*}
$$

To keep the operating current to a minimum, it is recommended to select $R_{22}$ within a range of $180 \mathrm{k} \Omega$ to $360 \mathrm{k} \Omega$. The sum of $R_{22}$ and $R_{21}$ should not exceed $1 \mathrm{M} \Omega$.
Route the ADJ2 line away from noise sources, such as the inductor or the SW2 line. In case the interface is used for converter2, connect ADJ2 pin directly to $\mathrm{V}_{\text {OUT2 }}$

Figure 34. Typical Application Circuit 1.5V/2.85V Adjustable Outputs

## OUTPUT FILTER DESIGN (INDUCTOR AND OUTPUT CAPACITOR)

The device is optimized to operate with inductors of $2.2 \mu \mathrm{H}$ to $4.7 \mu \mathrm{H}$ and output capacitors of $10 \mu \mathrm{~F}$ to $22 \mu \mathrm{~F}$. For operation with a $2.2 \mu \mathrm{H}$ inductor, a $22 \mu \mathrm{~F}$ capacitor is suggested.

## APPLICATION INFORMATION (continued)

## Inductor Selection

The selected inductor has to be rated for its DC resistance and saturation current. The DC resistance of the inductance will influence directly the efficiency of the converter. Therefore an inductor with lowest DC resistance should be selected for highest efficiency.
Equation 6 calculates the maximum inductor current under static load conditions. The saturation current of the inductor should be rated higher than the maximum inductor current as calculated with Equation 7. This is recommended because during heavy load transient the inductor current will rise above the calculated value.
$\Delta \mathrm{I}_{\mathrm{L}}=$ Vout $\times \frac{1-\frac{\text { Vout }}{\text { Vin }}}{\mathrm{L} \times f}$
$I_{\text {Lmax }}=I_{\text {outmax }}+\frac{\Delta I_{\mathrm{L}}}{2}$
With:
$f=$ Switching Frequency ( 2.25 MHz typical)
$\mathrm{L}=$ Inductor Value
$\Delta \mathrm{I}_{\mathrm{L}}=$ Peak to Peak inductor ripple current
$I_{\text {Lmax }}=$ Maximum Inductor current
The highest inductor current will occur at maximum Vin.
Open core inductors have a soft saturation characteristic and they can usually handle higher inductor currents versus a comparable shielded inductor.
A more conservative approach is to select the inductor current rating just for the maximum switch current of the corresponding converter. It must be considered, that the core material from inductor to inductor differs and will have an impact on the efficiency especially at high switching frequencies.
Refer to Table 5 and the typical applications for possible inductors.
Table 5. List of Inductors

| DIMENSIONS $\left[\mathrm{mm}^{\mathbf{3}}\right]$ | INDUCTOR TYPE | SUPPLIER |
| :---: | :---: | :---: |
| $3.2 \times 2.6 \times 1.0$ | MIPW3226 | FDK |
| $3 \times 3 \times 0.9$ | LPS3010 | Coilcraft |

| $3 \times 3 \times 1.4$ | LPS3015 | Coilcraft |
| $3.9 \times 3.9 \times 1.7$ | LPS4018 | Coilcraft |

## Output Capacitor Selection

The advanced fast response voltage mode control scheme of the two converters allow the use of small ceramic capacitors with a typical value of $10 \mu \mathrm{~F}$, without having large output voltage under and overshoots during heavy load transients. Ceramic X7R/X5R capacitors having low ESR values result in lowest output voltage ripple and are therefore recommended.
If ceramic output capacitors are used, the capacitor RMS ripple current rating will always meet the application requirements. The RMS ripple current is calculated as:

$$
\begin{equation*}
I_{\text {RMSCout }}=\text { Vout } \times \frac{1-\frac{\text { Vout }}{\text { Vin }}}{\mathrm{L} \times f} \times \frac{1}{2 \times \sqrt{3}} \tag{8}
\end{equation*}
$$

At nominal load current the inductive converters operate in PWM mode and the overall output voltage ripple is the sum of the voltage spike caused by the output capacitor ESR plus the voltage ripple caused by charging and discharging the output capacitor:

SLVS676A-JUNE 2006-REVISED JULY 2006

$$
\begin{equation*}
\Delta \text { Vout }=\text { Vout } \times \frac{1-\frac{\text { Vout }}{\operatorname{Vin}}}{\mathrm{L} \times f} \times\left(\frac{1}{8 \times \operatorname{Cout} \times f}+\mathrm{ESR}\right) \tag{9}
\end{equation*}
$$

Where the highest output voltage ripple occurs at the highest input voltage Vin.
At light load currents the converters operate in Power Save Mode and the output voltage ripple is dependent on the output capacitor value. The output voltage ripple is set by the internal comparator delay and the external capacitor. Higher output capacitors like $22 \mu \mathrm{~F}$ values minimize the voltage ripple in PFM Mode and tighten DC output accuracy in PFM Mode.

## Input Capacitor Selection

Because of the nature of the buck converter having a pulsating input current, a low ESR input capacitor is required for best input voltage filtering and minimizing the interference with other circuits caused by high input voltage spikes. The converters need a ceramic input capacitor of 10 uF . The input capacitor can be increased without any limit for better input voltage filtering.

## LAYOUT CONSIDERATIONS

As for all switching power supplies, the layout is an important step in the design. Proper function of the device demands careful attention to PCB layout. Care must be taken in board layout to get the specified performance. If the layout is not carefully done, the regulator could show poor line and/or load regulation, stability issues as well as EMI problems. It is critical to provide a low inductance, impedance ground path. Therefore, use wide and short traces for the main current paths as indicated in bold in Figure 35 .
The input capacitor should be placed as close as possible to the IC pins as well as the inductor and output capacitor.
Connect the GND Pin of the device to the PowerPAD of the PCB and use this Pad as a star point. For each converter use a common Power GND node and a different node for the Signal GND to minimize the effects of ground noise. Connect these ground nodes together to the PowerPAD (star point) underneath the IC. Keep the common path to the GND PIN, which returns the small signal components and the high current of the output capacitors as short as possible to avoid ground noise. The output voltage sense lines (FB 1, ADJ2, DEF-1) should be connected right to the output capacitor and routed away from noisy components and traces (e.g., SW line). If the EasyScale interface is operated with high transmission rates, the MODE/DATA trace must be routed away from the ADJ2 line to avoid capacitive coupling into the ADJ2 pin. A GND guard ring between the MODE/DATA pin and ADJ2 pin avoids potential noise coupling.

${ }^{(1)}$ The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.
${ }^{(2)}$ Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS \& no Sb/Br) - please check http://www.ti.com/productcontent for the latest availability information and additional product content details.
TBD: The Pb-Free/Green conversion plan has not been defined.
Pb -Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed $0.1 \%$ by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.
Pb -Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.
Green (RoHS \& no $\mathbf{S b} / \mathrm{Br}$ ): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine ( Br ) and Antimony (Sb) based flame retardants ( Br or Sb do not exceed $0.1 \%$ by weight in homogeneous material)
${ }^{(3)}$ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

THERMAL INFORMATION
This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to a ground or power plane (whichever is applicable), or alternatively, a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).
For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, Quad Flatpack No-Lead Logic Packages, Texas Instruments Literature No. SCBA017. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

B. This drawing is subject to change without notice.
C. Publication IPC-7351 is recommended for alternate designs.
D. This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat-Pack Packages, Texas Instruments Literature No. SCBA017, SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <http: //www.ti.com>.
E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
F. Customers should contact their board fabrication site for minimum solder mask web tolerances between signal pads.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to Tl's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with Tl's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.
