Buffered Voltage Output

TTL/CMOS Logic Compatible

24-Pin Narrow DIP Package

Requires No External Adjustments

Operates from Single or Dual Supplies

µP Compatible

General Description

Maxim's MX7228 contains eight 8-bit voltage output digital-to-analog converters (DACs) with separate input latches and output buffers for simple microprocessor and TTL/CMOS interfacing. The MX7228 maintains 8-bit accuracy over the full operating temperature range without external trimming.

Internally, data transfer into the data registers is via a common 8-bit TTL/CMOS compatible input bus. Logic inputs <u>A2</u>, A1, and A0 control which DAC is loaded after WR goes low.

Applications

Minimum Component Count Analog Systems

Digital Offset/Gain Adjustment

Industrial Process Control

Arbitrary Function Generators

Automatic Test Equipment

Typical Operating Circuit

Digital Inputs and Interface Logic

The digital inputs are compatible with both TTL and 5V CMOS logic, however the power supply current (I_{DD}) is somewhat dependent on input logic level. Supply current is specified for TTL input levels (worst case) but is reduced (by about 450 μ A) when the logic inputs are driven near GND or greater than 4 volts above GND.

Table 1 shows control logic truth table for \overline{WR} , A2, A1, and A0 operation. When WR is low, the input latch of the selected DAC is transparent, and the DAC's output responds to the activity on the data bus. The data is latched into the addressed DAC's latch on the rising edge of the WR signal. Figure 1 shows the timing diagram for the MX7228.

	Table	1.	Control	Logic	Truth	Table

Detailed Description

The MX7228 has eight matched voltage output digitalto-analog converters (DACs) The DACs are "inverted" R-2R ladder networks which convert 8 digital bits into equivalent analog output voltages in proportion to the applied reference voltage. All 8 DACs in the MX7228 share the same reference input (V_{REF}) and GND. A simplified circuit diagram of one of the eight DACs is provided in Figure 2.

V_{REF} Input

MX7228

The voltage at V_{REF} sets the full-scale output of the DACs. The input impedance of the V_{REF} pin is code dependent. The lowest value, approximately 2 kohms, occurs when the input code of all eight DACs is 01010101. The maximum value of infinity occurs when all of the input codes of the eight DACs is 0000000. Because the input resistance at V_{REF} is code dependent, the DACs' reference source should not have an output impedance more than 4 ohms. The capacitance at V_{REF} is also code dependent and typically varies from 120pF to 350pF.

 $V_{OUT1},\ V_{OUT2},\ V_{OUT3},\ V_{OUT4},\ V_{OUT5},\ V_{OUT6},\ V_{OUT7},$ and V_{OUT8} can be represented by a digitally programmable voltage source as:

$$V_{OUT} = Nb \times V_{REF}/256$$

where Nb is the numeric value of the DAC's binary input code.

Figure 1. Write Cycle Timing Diagram

Output Buffer Amplifiers

All voltage outputs are internally buffered by precision unity gain followers which slew at greater than 2V/µs. The output settles to $\pm 1/2$ LSB in less than 5µs when driving 2kΩ in parallel with 100pF with a full scale transition (0V to +10V or +10V to 0V) The buffers will also drive 2kΩ in parallel with 500pF to 10V levels without oscillation. Typical dynamic response and settling performance of the MX7228 are shown in Figures 3 and 4.

A simplified circuit diagram of an output buffer is shown in Figure 5. Input common mode range to GND is provided by a PMOS input structure. The output circuitry incorporates both a constant current source and an actively driven n-channel device. The actively driven n-channel device aids in discharging large output capacitances. The MX7228 can operate from either a single supply or dual supplies. The output buffer amplifiers are the only part of the MX7228 that receive V_{SS} power. Operating the MX7228 from dual supplies will improve the negative going output settling time near GND. In addition, the output amplifier can sink 500 μ A when operating with dual supplies. The use of dual supplies also extends the input reference voltage range. When operating with a single supply, the output sink current decreases when the output approaches 0 volts (see Figure 6).

The output amplifier broadband noise is approximately $50\mu N_{RMS}$ and is not strongly power supply voltage dependent. The output impedance of the output buffer is approximately 1Ω .

Applications Information

Power Supply and Reference Operating Ranges

The MX7228 is fully specified to operate between $\pm 12V \pm 10\%$ and $\pm 15V \pm 10\%$ (10.8V to 16.5V), and with +12V \pm 10% and +15V \pm 10% (10.0V to 10.5V), and with V_{SS} from 0V to -5.5V. 8 bit performance is guaranteed for single supply operation (V_{SS} = 0V), however, zero code error is improved with V_{SS} = -5V.

For adequate DAC and buffer operation, V_{REF} must always be below V_{DD} by at least 3.5V.

Power Supply Management

Careful PCB layout techniques should be used to minimize crosstalk between V_{REF} , GND, and the digital inputs. This is particularly important if the reference input is driven from an AC source. Bypass capacitors $(0.1\mu F$ in parallel with $6.8\mu F$) should be used between V_{C-r} and GND. (also between V_{res} and GND. if V_{res} V_{DD} and GND (also between V_{SS} and GND if V_{SS} is -5V).

Unipolar Output

In unipolar operation, the reference voltage is the same polarity as the output voltage. Since the reference voltage must always be positive with respect to GND, the output voltage is also positive with respect to GND. An example of a unipolar circuit configura-tion is shown in Figure 7. The unipolar code is given in Table 2.

Figure 8. Bipolar Output Circuit

Figure 9. Offset Circuit

M/X/M

Bipolar Output

Each DAC output may be configured for bipolar operation using the circuit in Figure 8. One op amp and two resistors are needed per channel. Table 3 shows the digital code versus output voltage for Figure 8 assuming R1=R2.

MSI		; co	ONTE	NT	S LS	8	ANALOG OUTPUT
1 1	1	1	1	1	1	1	$+V_{REF}\left(\frac{127}{128}\right)$
1 0) ()	0	0	0	0	1	$+V_{REF}\left(\frac{1}{128}\right)$
1 C	0	0	0	0	0	0	0V
0 1	1	1	1	1	1	1	$-V_{REF}\left(\frac{1}{128}\right)$
0 0	0	0	0	0	0	1	$-V_{REF}\left(\frac{127}{128}\right)$
0 0	0	0	0	0	0	0	$-V_{REF}\left(\frac{128}{128}\right) = -V_{REF}$

Table 3. Bipolar Code Table

Offsetting DAC Outputs

Each DAC can be offset using the circuit shown in Figure 9. If the op amp does not have a negative supply, then its common mode voltage range and output voltage range must include GND. Also, one DAC can provide the output offset for another DAC as shown in Figure 10.

Using an AC Reference

In applications where V_{REF} has AC signal components, the MX7228 has multiplying capabilities within the limits of the V_{REF} input range specifications. Figure 11 shows a technique for applying an AC signal to the MX7228. Since all eight DACs share a common reference, they all will be AC modulated. Output

distortion is typically less than 0.1% for frequencies up to 50kHz.

Generating V_{SS}

The performance of the MX7228 is specified with and without a V_{SS} supply. When the improved performance of dual supply operation is desired, but only a single supply is available, a negative supply can be generated using any of the circuits shown in Figure 12.

Digital Interface Applications

Figures 13 through 16 shown examples of interfacing the MX7228 to most popular microprocessors.

5V Operation

9

The MX7228 can also be used with a single 5V power supply or a \pm 5V power supply. The timing specifications are degraded, and the reference voltage range is reduced. The DNL of each DAC remains at \pm 1 LSB guaranteeing monotonicity. For devices with a negative offset and no negative supply there is a possibility, near zero, that the DAC will not change when the DAC code is incremented. Once the DAC has reached the offset voltage of the output buffer, the DAC will begin to increment in a normal fashion. Since the LSB voltage is only a few millivolts, care should be used in decoupling supplies, ground loops, etc.
